Abstract

We point out another important production channel of a light pseudoscalar Higgs boson a_1 via the decays of neutralinos, including $\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 a_1$, in the framework of the NMSSM. We scan the whole parameter space using the most up-to-date version of NMHDECAY and search for regions where $B(\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.5$. If the gluino and squarks are light enough for copious production of SUSY events at the LHC, there would be numerous number of $\tilde{\chi}_{2,3}^0$ in subsequent decays of gluinos and squarks. Therefore, the production rates of a_1 via neutralino decays would be more important than $h \rightarrow a_1 a_1$ and others. Potentially, the final state is filled with many τ leptons, which can be reconstructed at the mass of a_1 . This is a clean, observable, and distinguishable signature for NMSSM.

I. INTRODUCTION

Supersymmetry is the leading candidate for the physics beyond the standard model (SM). It not only solves the gauge hierarchy problem, but also provides a dynamical mechanism for electroweak symmetry breaking and a natural candidate for the dark matter. The minimal version, the minimal supersymmetric standard model (MSSM), has suffered from what so called little hierarchy problem and the μ problem.

An extension with an extra singlet superfield, known as the next-to-minimal supersymmetric standard model (NMSSM) was motivated to provide a natural solution to the μ problem. The μ parameter in the term $\mu H_u H_d$ of the superpotential of the MSSM naturally has its value at either M_{Planck} or zero (due to a symmetry). However, the radiative electroweak symmetry breaking conditions require the μ parameter to be of the same order as m_Z for fine-tuning reasons. Such a conflict was coined as the μ problem [1]. In the NMSSM, the μ term is generated dynamically through the vacuum-expectation-value (VEV), v_s , of the scalar component of the additional Higgs field S , which is naturally of the order of the SUSY breaking scale. Thus, an effective μ parameter of the order of the electroweak scale is generated.

The NMSSM was recently revived because it was shown that it can effectively relieve the little hierarchy problem [2]. Due to the additional Higgs singlet field and an approximate PQ symmetry, the NMSSM naturally has a light pseudoscalar Higgs boson a_1 . It has been shown [2] that, in most parameter space that is natural, the SM-like Higgs boson can decay into a pair of light pseudoscalar bosons with a branching ratio larger than 0.7. Thus, the branching ratio of the SM-like Higgs boson into $b\bar{b}$ would be less than 0.3 and so the LEP II bound is effectively reduced to around 100 GeV [3].

The dominance of $h \rightarrow a_1 a_1$ mode for the intermediate Higgs boson has significant impacts on the Higgs search strategies [4]. The most useful channel for intermediate Higgs boson, $h \rightarrow \gamma\gamma$ and $h \rightarrow WW^*$ would be substantially affected because $B(h \rightarrow \gamma\gamma)$ lowers by a factor of a few. So is the $h \rightarrow b\bar{b}$ in Wh, Zh production. New search modes via $h \rightarrow a_1 a_1$ are mandatory. For example, $h \rightarrow a_1 a_1 \rightarrow 4b$ for $m_{a_1} > 2m_b$ via Wh, Zh production with at least one charged lepton and $4B$ -tags in the final state has been shown to afford a clean signal of high significance and a full Higgs mass reconstruction at the LHC [5]. The associated Higgs production with gauge bosons or $t\bar{t}$ pairs was shown to be effective [6]. Similar studies

at the Tevatron were also performed [7]. Other possibilities like $h \rightarrow a_1 a_1 \rightarrow 2b2\tau$ [8] and $h \rightarrow a_1 a_1 \rightarrow 4\tau$ [8, 9] can further enhance the signal, especially when $2m_\tau < m_{a_1} < 2m_b$. In the extreme limit of zero mixing with the MSSM pseudoscalar, the singlet-like a_1 can decay into a pair of photons. In this case, $h \rightarrow a_1 a_1 \rightarrow 4\gamma$ [10]. The light pseudoscalar a_1 can also be produced in non-Higgs decays. It can be produced in B meson decays [11, 12, 13], in Υ decays [14] and other rare decays [15], and in associated production with chargino pair [16]. In some other contexts, a light pseudoscalar boson can also be frequently produced in association with a Higgs boson or a heavy quark pair [17]. There could also be other unconventional decay modes of the SM-like Higgs boson in the NMSSM, e.g., invisible decay into neutralinos [18]. A recent summary can be found in Ref. [19].

In this note we point out another important production channel of a light pseudoscalar Higgs boson a_1 via the decays of neutralinos, including $\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 a_1$, in the framework of the NMSSM. This is potentially much more important than from the decay of the Higgs boson or from the associated production. In particular, if the gluino and squarks are light enough for copious production of SUSY events at the LHC, there would be numerous number of $\tilde{\chi}_{2,3}^0$ in subsequent decays of gluinos and squarks. Therefore, the production rates of a_1 via neutralino decays would be much more important than $h \rightarrow a_1 a_1$ and others. There is also the possibility of $\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 h$ followed by $h \rightarrow a_1 a_1$. It was argued in Refs. [2] that the mass m_{a_1} in most favorable parameter space is lighter than $2m_b$, and thus $a_1 \rightarrow \tau^+ \tau^-$ is the most frequent. In this case, SUSY events would be filled with many τ leptons plus missing energies, with the corresponding $\tau^+ \tau^-$ reconstructed at the a_1 mass.

We scan the whole parameter space using the most up-to-date version of NMHDECAY [20] and search for regions where $B(\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.5$. We show characteristics of this region of parameter space.

II. TWO BODY AND THREE BODY DECAYS OF NEUTRALINO

The superpotential of the NMSSM is given by

$$W = \mathbf{h}_u \hat{Q} \hat{H}_u \hat{U}^c - \mathbf{h}_d \hat{Q} \hat{H}_d \hat{D}^c - \mathbf{h}_e \hat{L} \hat{H}_d \hat{E}^c + \lambda \hat{S} \hat{H}_u \hat{H}_d + \frac{1}{3} \kappa \hat{S}^3. \quad (1)$$

where $\hat{Q}$, $\hat{L}$, $\hat{H}_u$, $\hat{H}_d$, $\hat{U}^c$, $\hat{D}^c$, $\hat{E}^c$, and $\hat{S}$ are the doublet quark and lepton, doublet up-type Higgs and down-type Higgs, singlet up-quark and down-quark, and the singlet scalar

superfields, respectively.

The Higgs sector of the NMSSM consists of the usual two Higgs doublets H_u and H_d and an extra Higgs singlet S . The extra singlet field is allowed to couple only to the Higgs doublets of the model, the supersymmetrization of which is that the singlet field only couples to the Higgsino doublets. Consequently, the couplings of the singlet S to gauge bosons and fermions will only be manifest via their mixing with the doublet Higgs fields. After the Higgs fields take on the VEV's and rotating away the Goldstone modes, we are left with a pair of charged Higgs bosons, 3 real scalar fields, and 2 pseudoscalar fields. In particular, the mass matrix for the two pseudoscalar Higgs bosons P_1 and P_2 is

$$V_{\text{pseudo}} = \frac{1}{2} (P_1 \ P_2) \mathcal{M}_P^2 \begin{pmatrix} P_1 \\ P_2 \end{pmatrix} \quad (2)$$

with

$$\begin{aligned} \mathcal{M}_{P_{11}}^2 &= M_A^2, \\ \mathcal{M}_{P_{12}}^2 &= \mathcal{M}_{P_{21}}^2 = \frac{1}{2} \cot \beta_s \left(M_A^2 \sin 2\beta - 3\lambda\kappa v_s^2 \right), \\ \mathcal{M}_{P_{22}}^2 &= \frac{1}{4} \sin 2\beta \cot^2 \beta_s \left(M_A^2 \sin 2\beta + 3\lambda\kappa v_s^2 \right) \\ &\quad - \frac{3}{\sqrt{2}} \kappa A_\kappa v_s, \end{aligned} \quad (3)$$

where

$$M_A^2 = \frac{\lambda v_s}{\sin 2\beta} \left(\sqrt{2} A_\lambda + \kappa v_s \right), \quad (4)$$

and $\tan \beta = v_u/v_d$ and $\tan \beta_s = v_s/v$ and $v^2 = v_u^2 + v_d^2$. Here P_1 is the pseudoscalar in MSSM while P_2 comes from the singlet S and from the effects of rotating away the Goldstone modes. The pseudoscalar fields are further rotated to the diagonal basis (A_1, A_2) through a mixing angle [21]:

$$\begin{pmatrix} A_2 \\ A_1 \end{pmatrix} = \begin{pmatrix} \cos \theta_A & \sin \theta_A \\ -\sin \theta_A & \cos \theta_A \end{pmatrix} \begin{pmatrix} P_1 \\ P_2 \end{pmatrix} \quad (5)$$

where the masses of A_i are arranged such that $m_{A_1} < m_{A_2}$. At tree-level the mixing angle is given by

$$\tan \theta_A = \frac{\mathcal{M}_{P_{12}}^2}{\mathcal{M}_{P_{11}}^2 - m_{A_1}^2} = \frac{1}{2} \cot \beta_s \frac{M_A^2 \sin 2\beta - 3\lambda\kappa v_s^2}{M_A^2 - m_{A_1}^2}. \quad (6)$$

We also use a_1 to denote the A_1 . The a_1 is mainly the singlet when θ_A is small. The couplings of a_1 to fermions scale with $\sin \theta_A$ while a_1 can have large couplings to Higgsinos and Higgs bosons via the $\lambda SH_u H_d$ term of the superpotential.

We use the publicly available code, NMHDECAY [20], to generate parameter space points. Currently, the code has imposed a number of experimental constraints, including the radiative $b \rightarrow s\gamma$ decay, the B_d and B_s mixing parameters, $B_s \rightarrow \mu^+\mu^-$ decay, $B^+ \rightarrow \tau^+\nu_\tau$ decay, and the relic density of the lightest neutralino. These experimental constraints can be turned on or off. The parameter space points presented in this section satisfy all the above constraints. Before we show the decay branching ratios of the second lightest neutralino, we would like to give the vertex factor that we are considering. The vertex factor $a_1\text{-}\tilde{\chi}_i^0\text{-}\tilde{\chi}_j^0$ is given by

$$\begin{aligned} \mathcal{L} = & a_1 \overline{\tilde{\chi}_i^0} i\gamma^5 \tilde{\chi}_j^0 \left\{ \frac{g}{2} \sin \theta_A (N_{j2} - N_{j1} \tan \theta_w) (N_{i4} c_\beta - N_{i3} s_\beta) \right. \\ & \left. - \frac{\lambda}{\sqrt{2}} \sin \theta_A (N_{j3} c_\beta + N_{j4} s_\beta) N_{i5} + \frac{\lambda N_{j3} N_{i4} - \kappa N_{i5} N_{j5}}{\sqrt{2}} \cos \theta_A + (i \leftrightarrow j) \right\}. \quad (7) \end{aligned}$$

The other competing channels for $\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + X$ include $X = h_1, Z$, and 3-body decays via off-shell particles. The detailed formulas will be shown in a future publication [22]. The 3-body decays are suppressed as long as at least one of the 2-body modes are open. We show in Fig. 1 the branching ratios of $\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + (a_1, h_1, Z, 3\text{-body})$ for two sets of parameter space points, with varying κ and A_κ respectively. It is clear that $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + a_1)$ dominates in these two sets of points, which satisfy all experimental constraints and relic density of the LSP. The parameters κ and A_κ can be kept small by the approximate PQ and R symmetries, which guarantee the lightness of a_1 .

Experimentally, the decay $\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + a_1$ gives very interesting signatures. In typical SUSY events, a lot of gluinos or squarks are produced, which subsequently decay into the third or second lightest neutralinos, instead of directly decaying into the lightest one. Thus, there are numerous second lightest or third lightest neutralinos, which then decays into the lightest neutralino and the light pseudoscalar a_1 . The a_1 then decays into either $b\bar{b}$ or $\tau^+\tau^-$ depending on its mass. Therefore, the final state will be filled with many τ leptons, which can be carefully reconstructed at the mass of a_1 . This is a clean, observable, and distinguishable signature for NMSSM. *

* In gauge-mediated models, excessive production of τ leptons is often the signature. However, it can be

FIG. 1: Decay branching ratios for $\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + (a_1, h_1, Z, 3\text{-body})$ with (a) $\lambda = 0.15$, $A_\lambda = -500$ GeV, $A_\kappa = -0.1$ GeV, $\tan \beta = 10$, $\mu = -150$ GeV, $M_1 = 100$ GeV, and $M_2 = 200$ GeV versus κ ; (b) $\lambda = 0.2$, $A_\lambda = -500$ GeV, $\kappa = 0.03$, $\tan \beta = 5$, $\mu = -150$ GeV, $M_1 = 100$ GeV, and $M_2 = 200$ GeV versus A_κ .

III. DECAYS OF SQUARK INTO NEUTRALINOS

Here we show the relative branching ratios of a squark decaying into the lightest and second lightest neutralinos

$$\tilde{q}_{L,R} \rightarrow q_{L,R} \tilde{\chi}_{1,2}^0 \quad (8)$$

where we simply assume that the Yukawa coupling of the light quark is negligible compared with the gauge couplings. The couplings of $\tilde{q}_{L,R} q_{L,R} \tilde{\chi}_i^0$ are given by

$$\begin{aligned} g_{\tilde{u}_L u_L \tilde{\chi}_i^0} &= -\frac{g}{\sqrt{2}} \left(N_{i2} + \frac{t_w}{3} N_{i1} \right), & g_{\tilde{u}_R u_R \tilde{\chi}_i^0} &= \frac{gt_w}{\sqrt{2}} \frac{4}{3} N_{i1}, \\ g_{\tilde{d}_L d_L \tilde{\chi}_i^0} &= -\frac{g}{\sqrt{2}} \left(-N_{i2} + \frac{t_w}{3} N_{i1} \right), & g_{\tilde{d}_R d_R \tilde{\chi}_i^0} &= -\frac{gt_w}{\sqrt{2}} \frac{2}{3} N_{i1}. \end{aligned} \quad (9)$$

We scan the parameter space points with the requirements defined by NMHDECAY, except for the relic density of the lightest neutralino, and $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.5$ (details in the next section). With these parameter space points we calculate the squares of the relative gauge couplings:

$$|g_{\tilde{q}_{L,R} q_{L,R} \tilde{\chi}_2^0} / g_{\tilde{q}_{L,R} q_{L,R} \tilde{\chi}_1^0}|^2$$

distinguished between the gauge-mediated models and the NMSSM, because the right τ pair in NMSSM can be reconstructed at m_{a_1} but not for the τ leptons in GMSB models.

FIG. 2: Relative branching ratios of the left-handed or right-handed squark into a quark and the neutralinos: $|g_{\tilde{q}_{L,R} q_{L,R} \tilde{\chi}_2^0} / g_{\tilde{q}_{L,R} q_{L,R} \tilde{\chi}_1^0}|^2$. Under the requirements of NMHDECAY and $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.5$.

which can roughly indicate the relative branching ratios without taking into account the masses in the final state. We show in Fig. 2 the squares of relative gauge couplings. It is clear that the squarks, whether left-handed or right-handed, can frequently decay into the second lightest neutralino, instead of just directly into the lightest one. Therefore, it is consistent with what we have pointed out in the Introduction that there are numerous second or even the third lightest neutralinos via production of squarks or gluinos in SUSY events. They will then decay into the lightest neutralino and the light pseudoscalar Higgs boson a_1 . We will map the regions in parameter space that the branching ratio $B(\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.5$ in the next section.

IV. SCAN OF NMSSM PARAMETER SPACE

Here we scan for the parameter space using the most up-to-date version of NMHDECAY [20] in the following ranges of parameters

$$\begin{aligned}
\lambda &: 0 - 0.7, \quad A_\lambda: -1000 - 1000 \text{ GeV}, \\
\kappa &: -0.7 - 0.7, \quad A_\kappa: -10 - 10 \text{ GeV}, \\
\tan\beta &: 1 - 40, \quad \mu: -500 - 500 \text{ GeV}, \\
M_1 &: 0 - 1000 \text{ GeV}, \quad M_2: 0 - 1000 \text{ GeV},
\end{aligned} \tag{10}$$

where M_1 and M_2 are the bino and wino mass parameter, respectively. We ran for a total of 10 million random points in the parameter space. The successful points have to pass the criteria of NMHDECAY, including LEP II bounds, $b \rightarrow s\gamma$, B_d and B_s mixing, $B_s \rightarrow \mu^+\mu^-$ and $B^+ \rightarrow \tau^+\nu_\tau$, but not the LSP relic density. From the pool of successful points we then calculate the branching ratio of $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 a_1)$ and pick those with the branching ratio larger than 0.1. These points are shown in Fig. 3. It is easy to see those points with the branching ratio larger than 0.5 in the figure. We also show in Table I the reduction of the number of points under the requirements of NMHDECAY, and further under $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + a_1) > 0.1$ and 0.5, respectively.

V. CONCLUSIONS

In this note we have scanned the parameter space of the NMSSM with the help of the code NMHDECAY. In a sizable fraction of the parameter space points, shown in Table I, the branching ratio of $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 + a_1) > 0.5$. It indicates a potentially more important

Scanned after NMHDECAY	41,318
$B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.1$	3,260
$B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 a_1) > 0.5$	2,030

FIG. 3: Scatter plot in the plane of m_{a_1} and $B(\tilde{\chi}_2^0 \rightarrow \tilde{\chi}_1^0 a_1)$. The points pass the criteria of NMHDECAY and the branching ratio larger than 0.1.

production channel of the light pseudoscalar Higgs boson a_1 via the decays of neutralinos, including $\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 a_1$. It could be much more important than from the decay of the Higgs boson or from the associated production. In particular, if the gluino and squarks are light enough for copious production of SUSY events at the LHC, there would be numerous number of $\tilde{\chi}_{2,3}^0$ in subsequent decays of gluinos and squarks. The a_1 then decays into either $b\bar{b}$ or $\tau^+\tau^-$ depending on its mass. Therefore, the final state will be filled with many τ leptons, which can be carefully reconstructed at the mass of a_1 . This is a clean, observable, and distinguishable signature for NMSSM. There is also the possibility of $\tilde{\chi}_{2,3}^0 \rightarrow \tilde{\chi}_1^0 h$ followed by $h \rightarrow a_1 a_1$, which again gives rise to multi- τ -lepton final states.
